Multimodal Transformer Distillation for Audio-Visual Synchronization

Chung-Che Wang Hung-yi Lee Jyh-Shing Roger Jang **Xuanjun Chen** Haibin Wu National Taiwan University

Introduction

Audio-Visual Synchronization (AVS)

- Goal: Determine whether the mouth and speech are synchronized
- VocaLiST: A SOTA model as shown the teacher model in Figure 1
- Applications: Most audio-visual applications, such as dubbing
- Challenges: Requires high computing resources

Contributions

- Proposed an MTDVocaLiST model, which is trained by our proposed Multimodal Transformer Distillation (MTD) loss
- MTD encourages MTDVocaLiST to mimic the cross-attention distribution and value-relation of VocaLiST deeply
- MTDVocaLiST outperforms similar-size models, reducing VocaLiST's size by 83.52% while maintaining similar performance

MTDVocaLiST

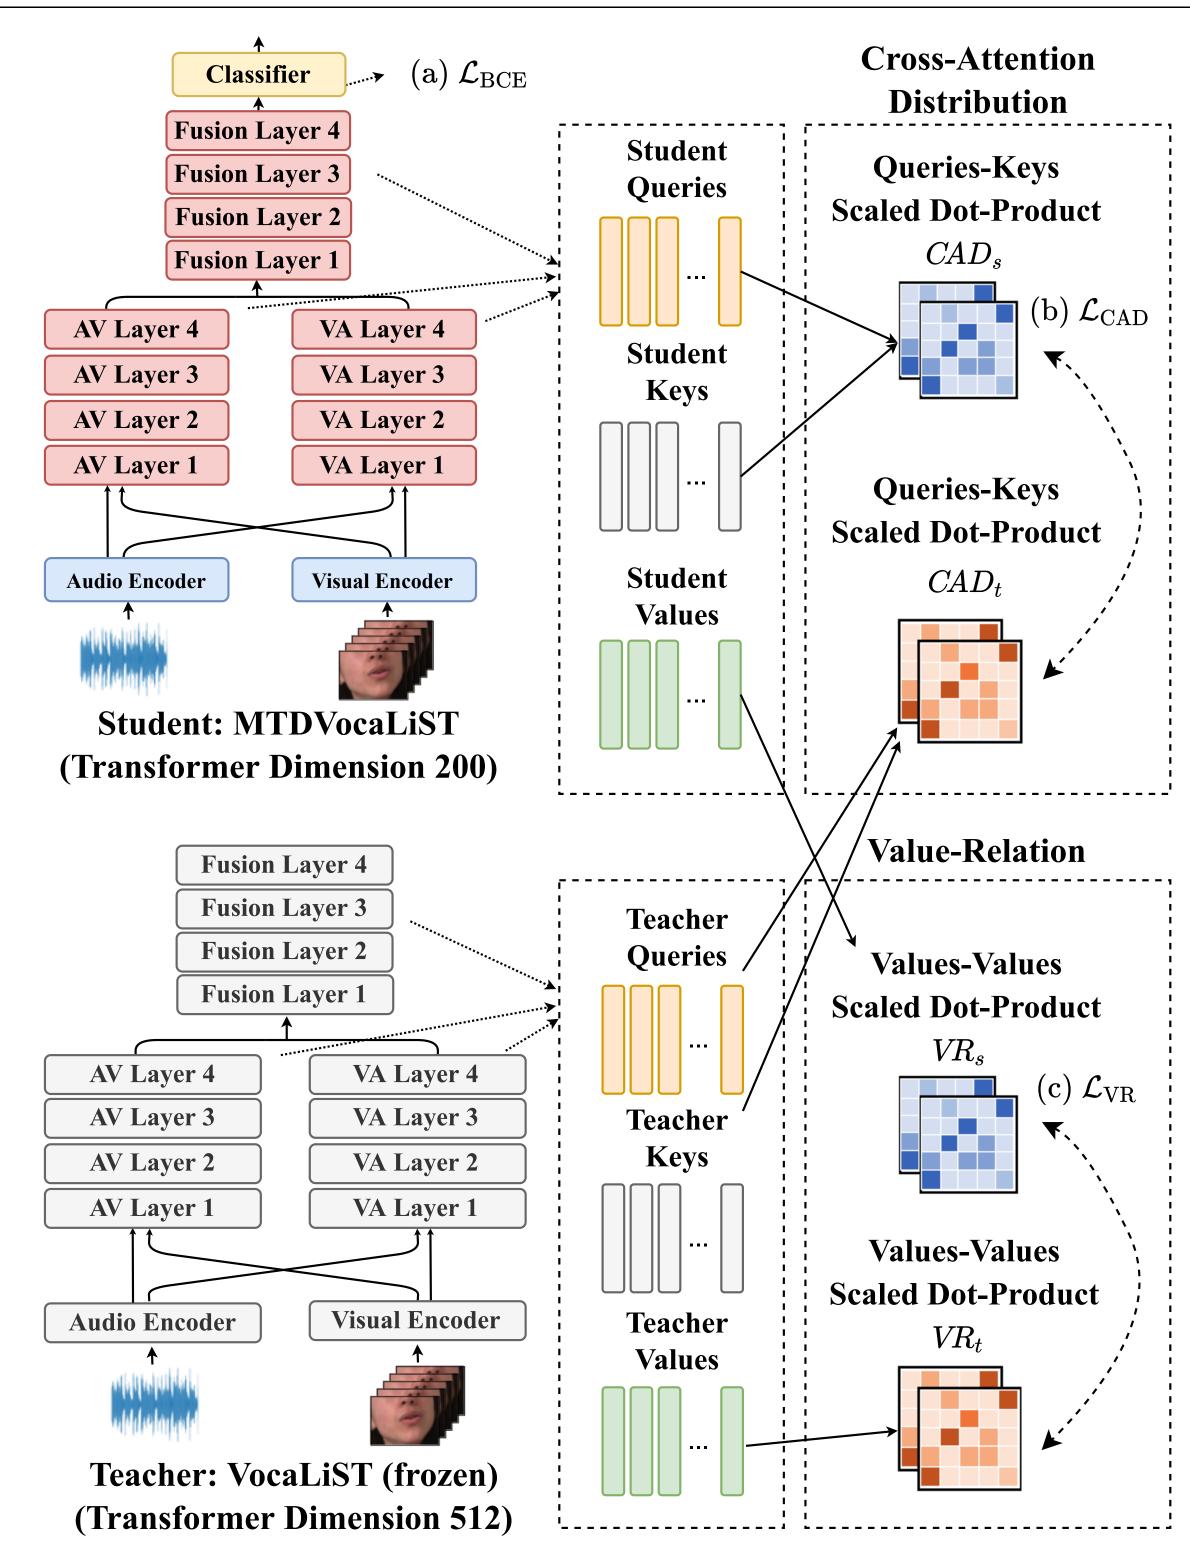

Figure 1. The proposed MTDVocaLiST model. (a) binary cross entropy loss. (b) cross-attention distribution distillation loss. (c) value-relation distillation loss.

Naïve Multimodal Transformer Distillation (NMTD)

$$\mathcal{L}_{NMTD} = w_0 \cdot \mathcal{L}_{BCE} + \sum_{l}^{L} w_{l1} \cdot \mathcal{L}_{CAD_l} + \sum_{l}^{L} w_{l2} \cdot \mathcal{L}_{VR_l}, \tag{1}$$

- w_0 , w_{l1} , and w_{l2} represent the weights for \mathcal{L}_{BCE} , \mathcal{L}_{CAD_l} , and \mathcal{L}_{VR_l}
- L denotes a candidate layer set, l-th is the sub-layer in the set Multimodal Transformer Distillation (MTD)
- After utilizing uncertainty weighting [1], overall MTD is as follows:

$$\mathcal{L}_{MTD} = w_0 \cdot \mathcal{L}_{BCE} + \sum_{\tau}^{T} \frac{1}{2 \cdot w_{\tau}^2} \cdot \mathcal{L}_{\tau} + \sum_{\tau}^{T} ln(1 + w_{\tau}^2), \tag{2}$$

- T represents a task set
- $\mathcal{L}_{ au}$ denotes the au-th loss, which could be the \mathcal{L}_{CAD} or \mathcal{L}_{VR} loss
- w_0 and w_τ are learnable parameters. $ln(1+w_\tau^2)$ serves to enforce positive regularization values

Experiment setup

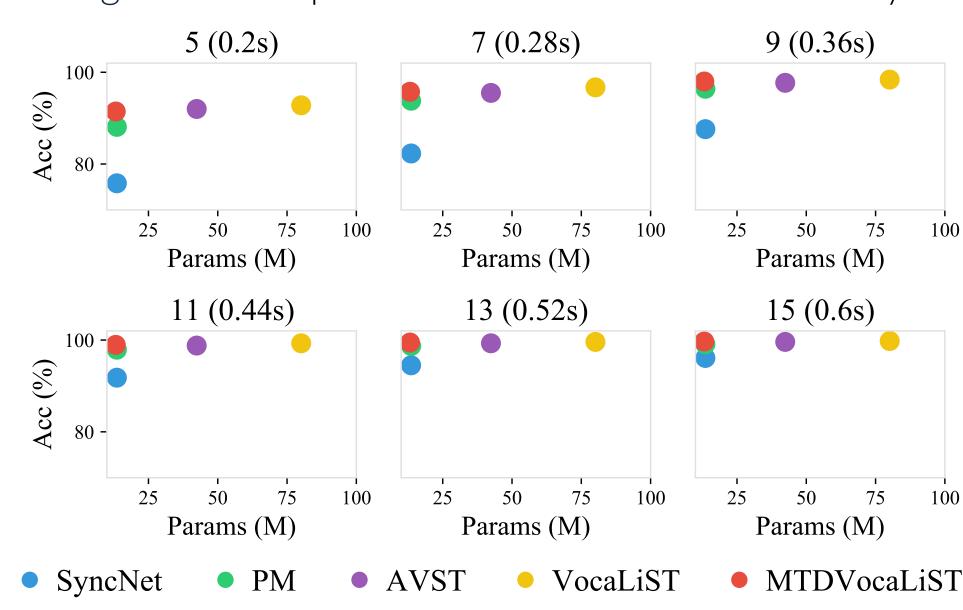

- Dataset: Lip Reading Sentences 2 (LRS2) dataset
- Training: Positive and negative samples are sampled on the fly
- Evaluation protocol: Accuracy of the cross-modal retrieval task

Main results

Table 1. Accuracy of different distillation methods in evaluation.

Distillation method	Input frame length (seconds)					
	5 (0.2s)	7 (0.28s)	9 (0.36s)	11 (0.44s)	13 (0.52s)	15 (0.6s)
\mathcal{L}_{BCE}	71.36	81.44	88.84	93.41	96.19	97.69
KD	80.87	88.62	93.48	96.32	97.90	98.82
RKD	86.06	92.42	95.95	97.80	98.75	99.29
MiniLM*	85.60	92.03	95.91	97.72	98.72	99.25
FitNets	90.81	95.48	97.77	98.81	99.42	99.66
MTD	91.45	95.75	97.99	98.95	99.46	99.68

Figure 2. Comparison of model size and accuracy.

Comparison with Different Distillation Methods (Table 1)

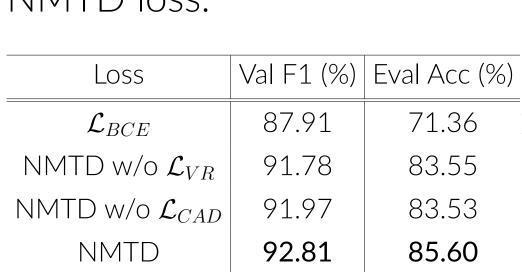

- Length 5: \mathcal{L}_{BCE} results in the lowest accuracy at 71.36%.
- Length 5: MTD significantly improves accuracy, surpassing KD by 10.58%, RKD by 5.39%, MiniLM* by 5.85%, and FitNets by 0.64%.
- Similar trends are observed across different input frame lengths.

Comparison with SOTA models (Figure 2)

- MTDVocaLiST outperforms similar-size SOTA models, SyncNet, and Perfect Match models by 15.65% and 3.35%;
- MTDVocaLiST reduces the model size of VocaLiST by 83.52%, yet still maintaining similar performance.

Ablation study and analysis

Figure 3. Ablation study of NMTD loss.

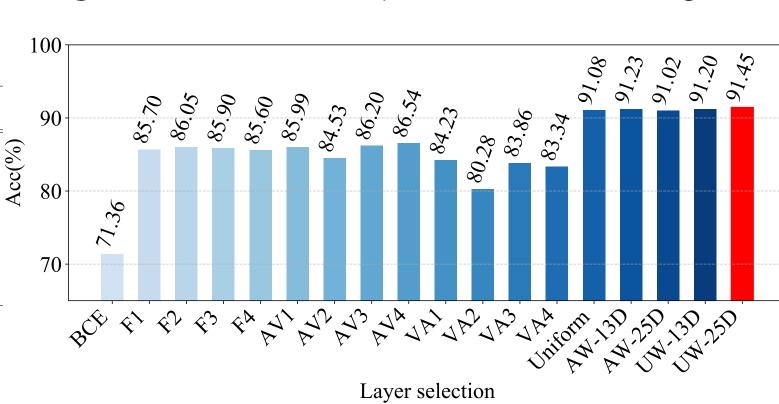

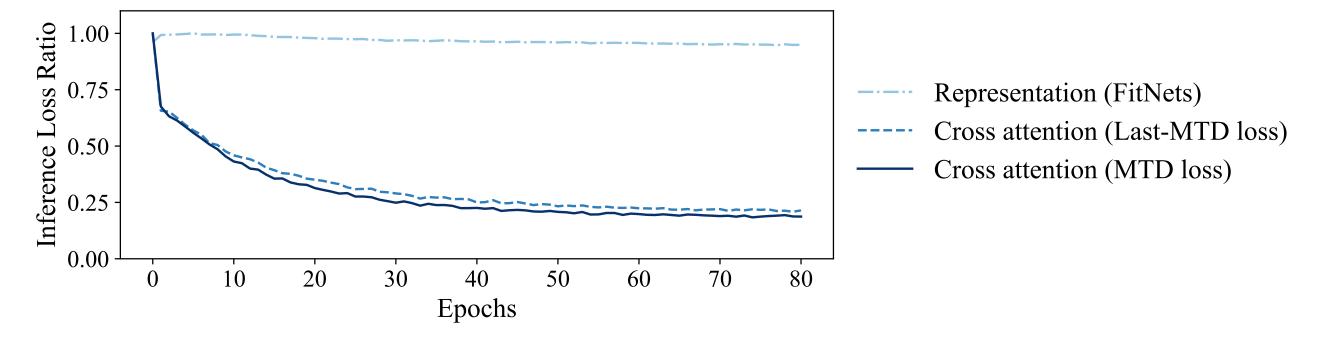

Figure 4. Different layer selection strategies.

Figure 5. Comparison of Transformer representation and cross-attention loss in inference. Note that the MTDVocaLiST only optimizes the MTD loss during training.

Indispensability (Figure 3): Both cross-attention distribution and value-relation contribute significantly to NMTD loss

Layer selection (Figure 4)

- Distilling any Transformer layer significantly improves performance.
- VA layers contribute minimally to the student's final performance.
- Single-layer distillation and BCE training perform worse.

• UW-25D layer weighting outperforms Uniform, AW and UW-13D Transformer behavior and Transformer representation (Figure 5)

• The Transformer representation loss will not decrease along with the cross attention loss in the inference of MTDVocaLiST
